

# Quantum Dynamics of Domain Walls in Molecular Magnets

D. A. Garanin and E. M. Chudnovsky  
Lehman College, City University of New York

## Quantum Dynamics of Domain Walls in Molecular Magnets

## Our main point:

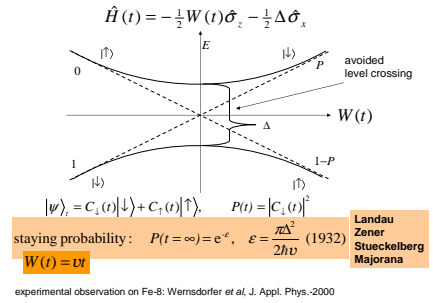

Tunneling relaxation in MMs can occur via self-induced resonance tuning of the dipolar field leading to a propagating front of Landau-Zener transitions.

- For large external bias this is quantum deflagration (with heating added)
- For small external bias this is propagation of quantum domain walls

Here we concentrate on quantum domain walls near the zero-field tunneling resonance. Domain walls and the underlying ordering are due to the DDI.

<sup>1</sup> Investigated and observed on several MMs (Fernandez & Alonso; Martínez Hidalgo, Chudnovsky and Anahory; Luis et al; Morello et al; Belesi, Borsa and Powell)

## Landau-Zener Effect

\*Magnetization\*:  $\sigma = \langle \psi | \hat{\sigma} | \psi \rangle$ ,  $\sigma_z(t) = |C_+|^2 - |C_-|^2 = 1 - 2P(t)$

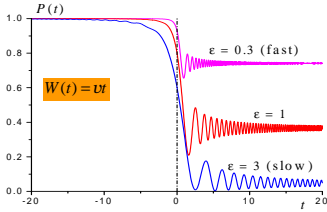

Landau-Lifshitz equation for the LZ effect:

$$\dot{\sigma} = \frac{1}{\hbar} [\sigma \times A(t)], \quad A(t) = e W(t) + e \Delta$$

Is equivalent to the Schrödinger equation!

Connection: LZ effect ↔ DW dynamics

Time dependence:

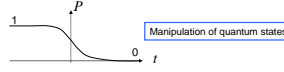

## Time-nonlinear LZ problems

- Inverse Landau-Zener problem

given  $P(t) \xrightarrow{?} W(t)$

Exact solution: Garanin & Schilling, EPL-2002

- Self-consistent LZ problem –  $W(t)$  created by transitions of other spins

Example: Domain walls in ferromagnets. Self-consistent time-dependent field on a spin results in a complete LZ transition. Exact analytical Walker solution for the dissipationless DW motion – Döring mass of the DW

Moving DW ↔ LZ front

In general, LZ transition is incomplete and there are excitations behind the front

## Formulation of the model

Equation of motion:

Use density-matrix equation for a pseudospin 1/2 coupled to bath. With

$$\sigma = \text{Tr}(\rho \hat{\sigma}), \quad \hbar \dot{\omega}_0 = A(t) = e W(t) + e \Delta$$

one obtains

$$\dot{\sigma} = [\sigma \times \omega_0] - \frac{\Gamma}{2} \left( \sigma - \frac{\omega_0 \cdot \sigma}{\omega_0} \frac{\omega_0}{\omega_0} \right) - \Gamma \frac{\omega_0 \cdot \sigma}{\omega_0} \sigma^{\text{eq}}$$

Here  $\Gamma$  is the relaxation rate and

$$\sigma^{\text{eq}} = \tanh \frac{\hbar \omega_0}{2k_B T}$$

is the equilibrium magnetization

Becomes Curie-Weiss equation

Dipolar field:  $W = g\mu_B S(B_z + B_z^{(D)}) = W_{\text{ext}} + W^{(D)}$

where  $W^{(D)} = E_D D_{zz}$ ,  $E_D = \frac{(g\mu_B S)^2}{v_0}$ ,  $D_{zz} = \sum_j \phi_j \sigma_{jz}$

and  $\phi_j = v_0 \frac{3(\mathbf{e}_j \cdot \mathbf{n}_j)^2 - 1}{r_j^3}$ ,  $\mathbf{n}_j = \frac{\mathbf{r}_j}{r_j}$

Uniformly magnetized ellipsoid:  $D_{zz} = \sigma_z \sum_j \phi_j \equiv \bar{D}_{zz} \sigma_z$ ,  $v_0^{1/3} \ll r \ll L$

Shape dependence  $\bar{D}_{zz}^{(\text{ell})} = \bar{D}_{zz}^{(\text{sph})} + 4\pi v (\chi - n_z)$

$n_z$  – demagnetizing factor

$v$  – number of sublattices, 2 for Mn12

$$\bar{D}_{zz}^{(\text{ell})} = \begin{cases} 0, & \text{simple cubic} \\ 2.155, & \text{Mn}_{12} \text{ (body centered tetragonal)} \\ 4.072, & \text{Fe}_8 \end{cases} \Rightarrow \bar{D}_{zz}^{(\text{sph})} = 10.53$$

## Magnetic ordering

For  $\Delta \ll E_D D_{zz}$  the Curie-Weiss equation reads

$$\sigma_z(z) = \tanh \left( \frac{E_D}{2k_B T} D_{zz}(z) \right)$$

Uniform solution:  $D_{zz} = \bar{D}_{zz} \sigma_z \Rightarrow T_C = E_D \bar{D}_{zz} / k_B$

For Mn<sub>12</sub>  $E_D / k_B \approx 0.0671$  K

Thus for a Mn<sub>12</sub> cylinder:  $T_C \approx 0.782$  K

comparable with the experimental value 0.9 K, F. Luis et al, PRL-2005

## Static domain wall

1d approximation

Inhomogeneously magnetized long cylinder of radius  $R$ :

$$D_{zz}(z) = \nu \int_{-L/2}^{L/2} dz' \frac{2\pi R^2 \sigma_z(z')}{[(z'-z)^2 + R^2]^{3/2}} - k\sigma_z(z)$$

where

$$k \equiv 8\pi\nu/3 - \bar{D}_{zz}^{(\text{sph})} = 4\pi\nu - \bar{D}_{zz}^{(\text{sph})} > 0,$$

$$k = 14.6 \text{ for Mn}_{12} \text{ and } k = 4.31 \text{ for Fe}_8$$

the Curie-Weiss equation

$$\sigma_z(z) = \tanh \left( \frac{E_D}{2k_B T} D_{zz}(z) \right)$$

is an integral equation!

$\sigma_z$  is due to  $\Delta$  and very small, the DW is linear (sing-like)

## Numerical solution for the DW profile

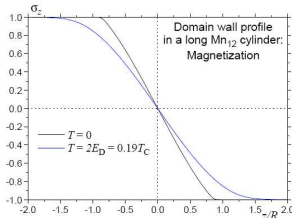

FIG. 1: Magnetization profile of a domain-wall in a Mn<sub>12</sub> cylinder at two different temperatures.

## Domain-wall mobility

For small  $B_z$  the DW speed  $v_{\text{DW}}$  is linear in  $B_z$

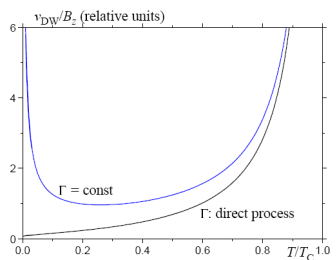

$$v_{\text{DW}} \equiv \mu_{\text{DW}} B_z, \quad \mu_{\text{DW}} \propto \begin{cases} 1/\Gamma, & \text{standard DWs with } |\mathbf{m}| = \text{const} \\ \Gamma, & |\mathbf{m}| \neq \text{const} \text{ (linear DWs)} \end{cases}$$

DW mobility  $\mu_{\text{DW}}$  follows from the static DW profile from the energy balance:

$$v_{\text{DW}} = \frac{S \sigma_{\infty} g \mu_B B_z}{\hbar \Gamma T} \left[ \int_{-\infty}^{\infty} dz' \frac{1}{\Gamma} \frac{1}{1 - \sigma_z^2} \left( \frac{d\sigma_z}{dz'} \right)^2 \right]^{-1}$$

Direct phonon processes:

$$\Gamma = \frac{S^2 \Delta^2 \omega_0 (g \mu_B \hbar)^2}{12 \pi E_t^4} \coth \frac{\hbar \omega_0}{2k_B T}$$

At, e.g.,  $S = 10$ ,  $B_z = 0.1$  T,  $T = 1$  K, and  $R = 1$  mm, this gives  $v_{\text{DW}} \sim 1$  m/s for  $(\Gamma) = 10^3$  s<sup>-1</sup> and  $v_{\text{DW}} \sim 10^3$  m/s for  $(\Gamma) = 10^6$  s<sup>-1</sup>.
